

## Section 1: Shape, geometrical constructions, circle theorem

### Notes and examples

These notes contain subsections on

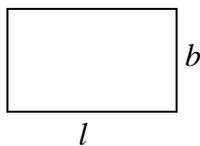

- [Revision: Perimeters, areas and volumes](#)
- [Pythagoras' theorem](#)
- [Angle properties of parallel and intersecting lines](#)
- [Angles in triangles and polygons](#)
- [Circle theorems](#)
- [Geometrical proofs](#)

### Revision: Perimeters, areas and volumes

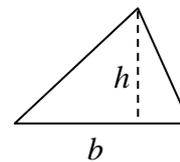

You are expected to be able to find perimeters, areas and volumes of simple shapes.

You should know the formulae given below:

Area of a rectangle =  $lb$

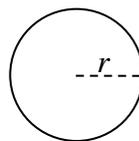

Area of a triangle =  $\frac{1}{2}bh$

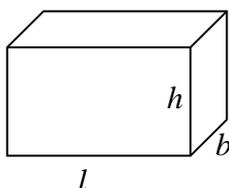

Circumference of a circle =  $2\pi r$

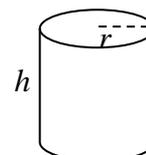

Area of a circle =  $\pi r^2$

Volume of a cuboid =  $lbh$

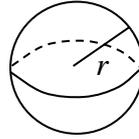

Volume of a cylinder =  $\pi r^2 h$

# AQA FM Geometry I 1 Notes and examples

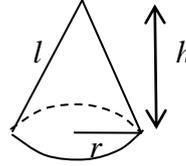

In addition, you will be given some formulae on your examination paper:

$$\text{Volume of sphere} = \frac{4}{3}\pi r^3$$

$$\text{Surface area of sphere} = 4\pi r^2$$

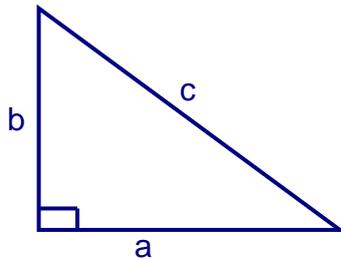

$$\text{Volume of cone} = \frac{1}{3}\pi r^2 h$$

$$\text{Curved surface area of cone} = \pi r l$$

## Pythagoras' theorem

Pythagoras' theorem can be used to find a missing side in a right-angled triangle.

In some right-angled triangles, the values of all three of  $a$ ,  $b$  and  $c$  are integers. Sets of three integers  $a$ ,  $b$  and  $c$  which satisfy Pythagoras' theorem are called Pythagorean triples.

Some well-known ones which you should recognise are:

3, 4, 5	$3^2 + 4^2 = 9 + 16 = 25 = 5^2$
5, 12, 13	$5^2 + 12^2 = 25 + 144 = 169 = 13^2$
8, 15, 17	$8^2 + 15^2 = 64 + 225 = 289 = 17^2$
7, 24, 25	$7^2 + 24^2 = 49 + 576 = 625 = 25^2$

Multiples of these also form Pythagorean triples, e.g. 6, 8, 10.

### Example 1

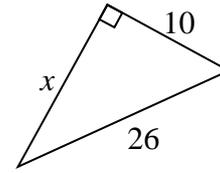

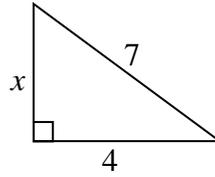

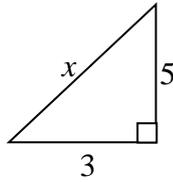

Find the sides marked  $x$  in the triangles below.

(i)

(ii)

(iii)

# AQA FM Geometry I 1 Notes and examples

## Solution

(i)  $3^2 + 5^2 = x^2$

$$9 + 25 = x^2$$

$$x^2 = 34$$

$$x = \sqrt{34} = 5.83 \text{ (3 s.f.)}$$

(ii)  $x^2 + 4^2 = 7^2$

$$x^2 + 16 = 49$$

$$x^2 = 33$$

$$x = \sqrt{33} = 5.74 \text{ (3 s.f.)}$$

- (iii) The sides of this triangle form a Pythagorean triple: the hypotenuse is 26 ( $2 \times 13$ ) and one of the other sides is 10 ( $2 \times 5$ ). Using the triple 5, 12, 13, the sides of the triangle are 10, 24, 26, and so  $x = 24$ .

You could work this out using Pythagoras' theorem as in (ii), but spotting the Pythagorean triple saves time!

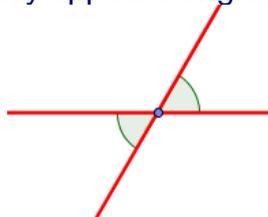

## Angle properties of parallel and intersecting lines

You should already be familiar with some important angle facts:

- Angles on a straight line add up to  $180^\circ$
- Angles round a point add up to  $360^\circ$

You may also have met some of the following angle properties, for angles found in parallel and intersecting lines.

- Vertically opposite angles are equal

Vertically opposite angles form an 'X' shape

- Corresponding angles are equal

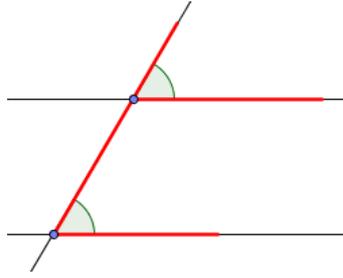

3 of 9

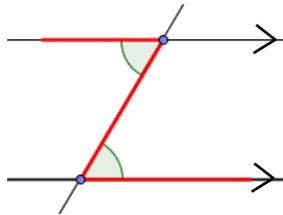

Corresponding angles form an 'F' shape – this may be back-to-front or upside down!

# AQA FM Geometry I 1 Notes and examples

- Alternate angles are equal

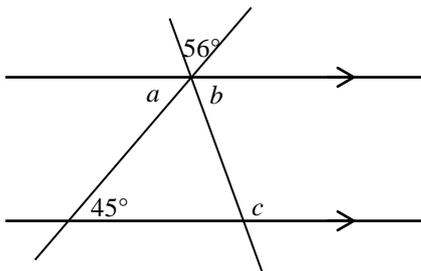

Alternate angles form an 'Z' shape – this may be back-to-front!

Combining these angle properties with the rules about angles on a straight line and angles round a point allow you to solve problems in which you need to find missing angles.

## Example 2

Find the angles marked  $a$ ,  $b$  and  $c$  in the diagram below.

## Solution

Angle  $a$  and the  $45^\circ$  angle are alternate angles ('Z' shape) so  $a = 45^\circ$ .

The angle vertically opposite to the  $56^\circ$  angle is also  $56^\circ$ .

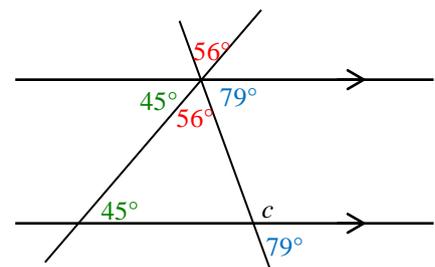

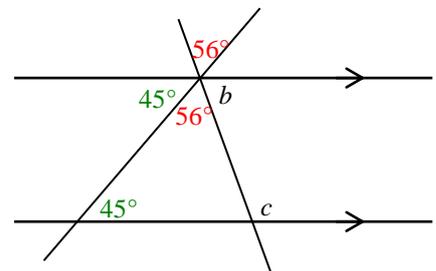

Angles on a straight line add up to  $180^\circ$

$$\text{so } 45^\circ + 56^\circ + b = 180^\circ$$

$$\text{So } b = 79^\circ.$$

The angle corresponding to  $b$  ('F' shape) is also  $79^\circ$ :

Angle  $c$  and the  $79^\circ$  angle form a straight line, so  $c = 101^\circ$ .

## Angles in triangles and polygons

You should already know the rules for angles in triangles and quadrilaterals:

- Angles in a triangle add up to  $180^\circ$
- Angles in a quadrilateral add up to  $360^\circ$

You may also know how to find angles in regular polygons, by splitting the polygon into triangles:

This regular pentagon is split up into 3 triangles. Since the sum of the angles of each triangle is  $180^\circ$ , the total of the angles in the pentagon is  $3 \times 180^\circ = 540^\circ$ . So each of the interior angles of the pentagon is  $\frac{540}{5} = 108^\circ$ .

You can use a similar technique for any regular polygon. An  $n$ -sided polygon can be split into  $n - 2$  triangles.

### Example 3

Find the interior angle of a regular decagon (10 sides).

### Solution

The sum of the interior angles =  $8 \times 180^\circ = 1440^\circ$ .

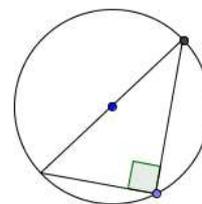

Each interior angle =  $\frac{1440}{10} = 144^\circ$

## Circle theorems

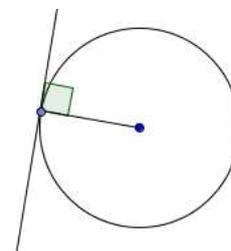

There are several theorems about circles which you will need to know.

Three of these are covered in the Circles section within the Coordinate geometry topic:

- The angle in a semicircle is a right-angle

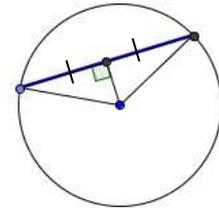

- A tangent to a circle is perpendicular to the radius at that point

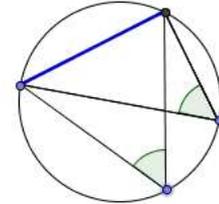

# AQA FM Geometry I 1 Notes and examples

- A line from the centre perpendicular to a chord bisects the chord

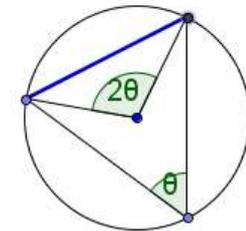

You also need to know four other results about angles in circles:

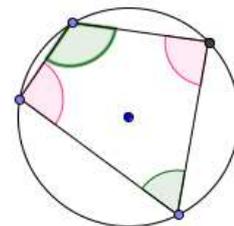

- Angles subtended by the same chord in the same segment are equal

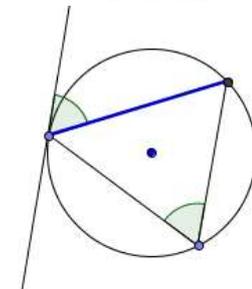

- The angle subtended in the centre by a chord is twice the angle subtended at the circumference

- Opposite angles in a cyclic quadrilateral add up to  $180^\circ$  (a cyclic quadrilateral has all four corners on the edge of a circle)

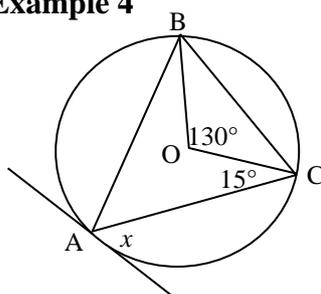

- The alternate segment theorem: the angle between a chord and a tangent is equal to the angle subtended by the chord

You can see all these circle theorems demonstrated in the Geogebra resource [Angles in circles](#).

## Example 4

O is the centre of the circle, and a tangent to the circle at A is shown. Find the angle marked  $x$ .

# AQA FM Geometry I 1 Notes and examples

## Solution

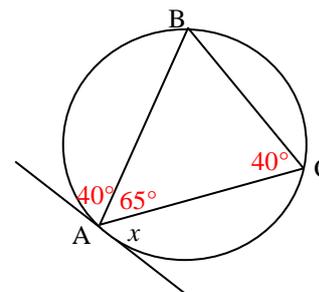

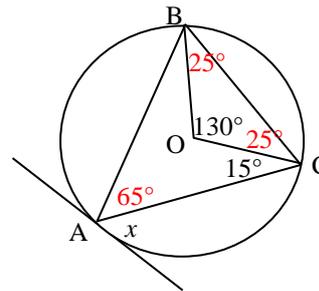

The angle subtended at the centre by BC is  $130^\circ$ , so the angle subtended at the circumference by BC is  $65^\circ$ .

Since OB and OC are both radii, triangle OBC is an isosceles triangle and so the other two angles are equal. Since the angles in a triangle add up to  $180^\circ$ , these angles are therefore  $25^\circ$ .

So now we know that angle BCA is  $40^\circ$ .

Using the alternate segment theorem, we can mark another angle of  $40^\circ$  on the diagram.

Now, using angles on a straight line,  $40^\circ + 65^\circ + x = 180^\circ$   
So  $x = 75^\circ$ .

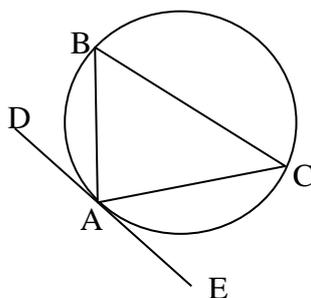

## Geometrical proofs

You have already covered algebraic proof in earlier sections. Sometimes you may need to prove something geometrically – using the theorems in this section.

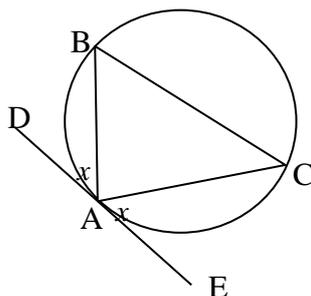

### Example 4

In the diagram below, DE is the tangent to the circle at A, and angle BAD is equal to angle CAE. Prove that BC is parallel to DE.

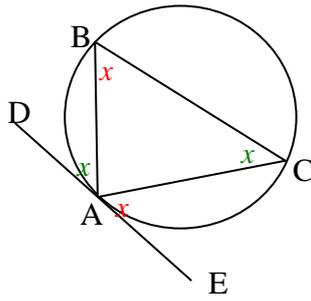

### Solution

Start by copying the diagram and marking in the equal angles.

Now, using the alternate segment theorem, angle BCA is equal to angle BAD, and angle CBA is equal to angle CAE.

## AQA FM Geometry I 1 Notes and examples

Since angles EAC and BCA are equal, they form alternate angles ('Z' shape), and so BC and DE must be parallel.

It is important in a proof question to explain each step carefully, otherwise you may lose marks.
